When individuals in the population have two parents, we will often have loops in the "genealogical tree". This means that the typical "genealogical tree" cannot be a tree.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

This leads us to consider the population (twice as big) of the chromosomes, since they have only a parent.

When adding recombination events to the ancestry, we obtain the Ancestral Recombination Graph, that contains all the contributions to the genome of the N individuals.

The ARG-inspired process

To extend the ARG, let look at the effect of a recombination event on the whole population (past, present, future). To keep our tree structure, we draw the genealogical tree for a specific locus x on the chromosome.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Example with x before the recombination point.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Now, with x after the recombination point.

Using the description of a recombination as a jump of ancestor, we can define a random process indexed by our parameter x:

- each individual (vertex) has a Poisson process
- at every tick of its Poisson, the individual choses himself a new ancestor uniformly on the previous generation

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Characteristics of the process

- The trees cannot have a lower bound
- We don't know if changes way down the tree can typically affect the tree near the present (we hope they don't)
- Is there a locus for which the genealogical tree doesn't have the usual properties (abnormally high number of ascendents, non-connexity...)?

Study of the process (done under the invariant laws)

Invariant laws

- Definition for the continuous-tree version of the processus
- Control of the depth of the most recent common ancestor (mrca)
- Control of the number of ancestors in a generation
- Regularity of the trajectories (càdlàg)
 - \blacktriangleright Defition of a distance on the space of trees rooted at $-\infty$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Prospects

Definition/convergence in law for more general initial distributions
